A Volumetric Analysis Complexometric Titration

Complexometric Titration or chelatometry is a type of volumetric analysis wherein the coloured complex is used to determine the endpoint of the titration. Titration is one of the common method used in laboratories which determines the unknown concentration of an analyte that has been identified. It is a method used in quantitative chemical analysis.

Complexometric titrations are used for determination of concentration of metal ions in solution. It is a volumetric analysis as volume of analyte, titrant and even indicator plays important role during titration. Indicators such as calcein and eriochrome black T etc. are used in complexometric titration.

Complexometric Titration Experiment - Principle, Procedure ...

Complexometric titration is a form of volumetric analysis in which the formation of a colored complex is used to indicate the end point of a titration. Complexometric titrations are particularly useful for the determination of a mixture of different metal ions in solution. An indicator capable of producing an unambiguous color change is usually used to detect the end-point of the titration.Complexometric titration are those reactions where a simple ion is transformed into a complex ion and the e

In volumetric analysis, chelating agents (such as ethylenediamine tetraacetic acid, EDTA) are often used as a reagents or as indicators for the titration of some metal ions. Because of the stability of chelates, polydentate ligands (also called chelating agents) are often used to sequester or remove metal ions from a chemical system.
